

# Abstract for Invert Sugar Production Line

*Ensymm Abstract for a Production Line of Invert Sugar*

# INVERT SUGAR

The food and drink industry heavily depends on enzymes. These kind of proteins produced by yeast have been used for thousands of years in brewing and baking. Invert sugar (IS) contains fructose and glucose in roughly equal proportions. The invert sugar is greater in demand than pure glucose as food and drink sweeteners, because fructose is sweeter than glucose.

Main consumers of invert sugar are the baking, beverages, canning, confectionery and dairy industries. In addition to this, high fructose syrup is used in many other processed foods like jams and jellies. However, it is being used only in biscuits and soft drinks. A manufacturer of IS expecting to supply it in next couple of years to the confectionery, fruit canning,

foods and dairy products industries as well. Fructose, also known as fruit sugar, is the sweetest natural sugar and is found in fruits, vegetables, and honey.

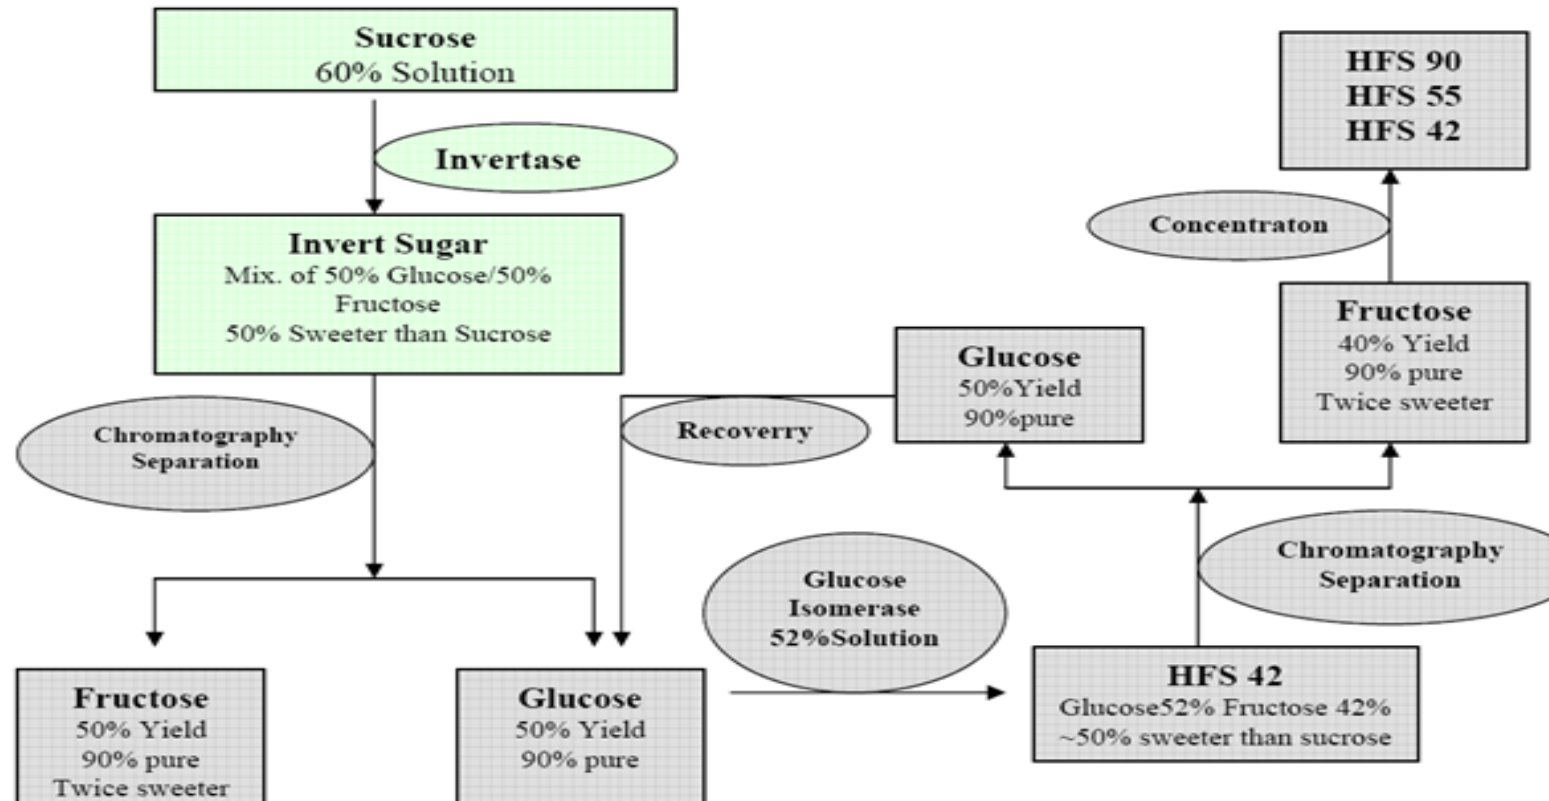

The body responds to fructose in a different way than to glucose and sucrose. Fructose is more satiating, and it is up to 1.8 times sweeter than sucrose, making it useful in foods and beverages for the health conscious. Fructose is also ideal for use in diabetic foods as it has very little effect on blood glucose and only a negligible effect on the secretion of insulin.

Enzymatic treatments are a now a major way producing sweeteners, including syrups derived from sucrose or starch that contain mixtures of glucose,

maltose, fructose, and other sugars. Glucose has 70-75% the sweetening strength of beet sugar (sucrose), but fructose is twice as sweet as sucrose. Thus, processes for the manufacture of fructose are of considerable value. Invertase is used traditionally in the production of inverted sugars for industry, especially in the manufacture of candies and preserves, production of lactic acid and ethanol production from fermentation of cane sugar molasses.

# INVERT SUGAR PATHWAY

## Process Pathway

# INVERT SUGAR AND PROPERTIES

Invert sugar is prepared by the hydrolysis of sucrose to glucose (dextrose) and fructose. This is achieved by subjecting a sucrose solution to acid and heat:

Invert sugar syrups can be fully inverted as above, or partially inverted to leave part of the original sugar unchanged. These syrups are known as medium or partial invert sugar syrups. The term "invert" originates from the effect on the polarimeter instrument traditionally used to analyze sucrose solutions. Compared to pure sucrose, a mixture of glucose and fructose "inverts" the plane of polarised light, and so this is known as invert sugar.

Inverting sugar in your own factory is a time consuming process that needs critical process control, and

can be difficult to manage in the busy production environment.

## Properties of Invert Sugar

Invert sugar has the following properties that provide benefits in many food applications:

### Sweetness

Medium invert (50% sugar, 50% invert) has an increase sweetness of 20%, when compared to pure sugar or pure invert. This additional sweetness can be of benefit in fruit flavored drinks where around 20% less carbohydrate sweetener can be used as ordinary sugar is replaced with medium invert. Enzymatic invert sugar is an absolutely health friendly sweetener. Herein, the enzyme invertase is employed for hydrolysis of sucrose into glucose

and fructose. Now, fructose is a sugar, which can be consumed even by diabetic patients due to the fact that its metabolism is insulin independent.

# PROPERTIES OF INVERT SUGAR

Moreover, invert sugar is 28-30% sweeter than table sugar so the amount of sugar required for a particular degree of sweetness is also reduced. Finally, enzymatic invert sugar does not involve the use of any chemicals or acids unlike the conventional acid-hydrolyzed invert syrup. Hence, it is a completely healthy sweetener.

## Sucrose Inversion Using Invertase

The conventional method of manufacturing invert sugar involves acid hydrolysis of sucrose, the popular and cheap sweetener. However, such acid hydrolysis has a low conversion efficiency, high-energy consumption and thus cost of production is high. The acid-hydrolyzed product also contains impurities introduced by uncontrollable parameters during inversion. This conversion can also

# PROPERTIES OF INVERT SUGAR

be achieved by enzymatic action of invertase on sucrose with a conversion efficiency of almost 100% without the inherent disadvantages of acid hydrolysis. The key to the developed process is a specific enzyme for the continuous production of concentrated invert sugar using immobilized yeast cells in an inorganic insoluble matrix.

Now, because of the feasible production of invertase can be used as free enzyme. The advantage against the hot acid process is:

- Near 100% yield
- Low temperature and thus low energy cost
- No impurity
- 1:1000 dosage

- Better taste of the product
- Easy handling
- Small stock

## Invertase Enzyme

The official name for invertase is beta-fructofuranosidase, which implies that the reaction catalyzed by this enzyme is the hydrolysis of the terminal non-reducing beta-fructofuranoside residues in beta-fructofuranosides. Note that alpha-D-glucosidase, which splits off a terminal glucose unit, can also catalyze this reaction. Note that sucrose can be hydrolyzed relatively easily. The reaction proceeds in an acidic environment without the interaction of invertase but with very low yield! The key to the developed process is a specific enzyme for the continuous

production of concentrated invert sugar using immobilized yeast cells in an inorganic insoluble matrix.

## Invert Sugar as Liquid Product

A considerable change in the market of sweetening of foods has been observed and the dominance of sucrose as a major carbohydrate sweetener has been challenged. A wide range of new and more desirable carbohydrate based sweeteners has emerged on the scene to keep pace with the advances in food technology. These sweeteners have wide applications in the food and pharmaceutical industries. The most important among them is invert sugar, an equimolecular mixture of glucose and fructose. Invert sugar is a

# PROPERTIES OF INVERT SUGAR

valuable sweetener in food and pharmaceutical application because of its functionally more desirable properties i.e. high osmotic pressure, high solubility and humid nature.

## Some of the important application of invert sugar are:

- Sweet-meat, bread, biscuits, chocolates, condensed milk, jams, jelly etc.
- Syrups in the pharmaceutical industry
- Beverages including aerated beverages
- As a substitute for honey
- Infant foods
- Intravenous injectables for treatment of certain pathological conditions such as diabetes
- In paper and tobacco industries because of its humectancy

# INVERT SUGAR PROCESS LINE AND USE

## Invert sugar can be used in:

- Biscuits: For caramelization and enhanced flavor.
- Better texture
- Bread, cakes & pastries: For better crust color and softer crumb and faster yeast activation.
- Fruit processing: For better shelf life due to good humectant properties. Provides better taste profile and enhances flavor.
- Honey: For bee feeding and blending with honey. Restricted bacterial activity. Good and chemically purer replacement of honey.
- Squashes, Lemonades and Instant Energy Drinks- Glucose and fructose provide instant energy and better taste.
- Pharmaceuticals-Ready to use for cough syrups and glucose and fructose based intravenous fluids.

## INVERT SUGAR CAN BE USED IN:

Enzymatic invert sugar is an absolutely health-friendly sweetener. Herein, the enzyme invertase is employed for hydrolysis of sucrose into glucose and fructose. Now, fructose is a sugar, which can be consumed even by diabetic patients. This is because its metabolism is insulin independent. Also, invert sugar is 28-30% sweeter than table sugar so the amount of sugar required for a particular degree of sweetness is also reduced. Finally, enzymatic invert sugar does not involve the use of any chemicals or acids unlike the conventional acid-hydrolyzed invert syrup. Hence, it is a completely healthy sweetener.

Sucrose can be inverted to an equimolar mixture of glucose and fructose called invert sugar. There are different methods of inversion among which acid inversion and bio-inversion are more popular. Bio-inversion though expensive, is a better alternative as it does not produce any polymerized byproducts as seen in case of acid inversion.

The conventional method of manufacturing invert sugar involves acid hydrolysis of sucrose, the popular and cheap sweetener. However, such acid hydrolysis has low conversion efficiency, high-energy consumption and thus cost

of production is high. The acid-hydrolysed product also contains impurities introduced by uncontrollable parameters during inversion. This conversion can also be achieved by enzymatic action of invertase on sucrose with a conversion efficiency of almost 100% without the inherent disadvantages of acid hydrolysis.

ensymm is a German based premier project consulting company for Life Sciences, serving biotech companies, pharmaceutical industry and food ingredient companies. We provide clients with a variety of business and technology consulting services as well as with specialized teams in various areas of our competence.
